AN ELEMENTARY AND UNIFIED PROOF OF GROTHENDIECK’S INEQUALITY

SHMUEL FRIEDLAND, LEK-HENG LIM, AND JINJIE ZHANG

Abstract. We present an elementary, self-contained proof of Grothendieck’s inequality that unifies the real and complex cases and yields both the Krivine and Haagerup bounds, the current best-known explicit bounds for the real and complex Grothendieck constants respectively. This article is intended to be pedagogical, combining and streamlining known ideas of Lindenstrauss–Pełczyński, Krivine, and Haagerup into one that requires only univariate calculus and basic complex variables.

1. Introduction

We will let $F = \mathbb{R}$ or $\mathbb{C}$ throughout this article. In 1953, Grothendieck proved a powerful result that he called “the fundamental theorem in the metric theory of tensor products” [8]; he showed that there exists a finite constant $K > 0$ such that for every $l, m, n \in \mathbb{N}$ and every matrix $M = (M_{ij}) \in F^{m \times n}$,

\[
\max_{\|x_i\|=\|y_j\|=1} \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} \langle x_i, y_j \rangle \right| \leq K \max_{|\varepsilon_i|=|\delta_j|=1} \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} \varepsilon_i \delta_j \right|
\]

where $\langle \cdot, \cdot \rangle$ is the standard inner product in $F^l$, the maximum on the left is taken over all $x_i, y_j \in F^l$ of unit 2-norm, and the maximum on the right is taken over all $\varepsilon_i, \delta_j \in F$ of unit absolute value (i.e., $\varepsilon_i = \pm 1$, $\delta_j = \pm 1$ over $\mathbb{R}$; $\varepsilon_i = e^{i\theta_i}$, $\delta_j = e^{i\phi_j}$ over $\mathbb{C}$). The inequality (1) has since been christened Grothendieck’s inequality and the smallest possible constant $K$ Grothendieck’s constant.

The value of Grothendieck’s constant depends on the choice of $F$ and we will denote it by $K^F_G$.

Over the last 65 years, there have been many attempts to improve and simplify the proof of Grothendieck’s inequality, and also to obtain better bounds for the Grothendieck constant $K^F_G$, whose exact value remains unknown. The following are some major milestones:

(i) The central result of Grothendieck’s original paper [8] is that his eponymous inequality holds with $\pi/2 \leq K^\mathbb{R}_G \leq \sinh(\pi/2)$ and $4/\pi \leq K^\mathbb{C}_G$. Grothendieck relied on the sign function for the real case and obtained the complex case from the real case via a complexification argument.

(ii) The power of Grothendieck’s inequality was not generally recognized until the work of Lindenstrauss and Pełczyński [14] 15 years later, which connected the inequality to absolutely $p$-summing operators. They elucidated and improved Grothendieck’s proof in the real case by computing expectations of sign functions and using Taylor expansions, although they did not get better bounds for $K^\mathbb{R}_G$.

(iii) Rietz [19] obtained a slightly smaller bound $K^\mathbb{R}_G \leq 2.261$ in 1974 by averaging over $\mathbb{R}^n$ with normalized Gaussian measure and using a variational argument to determine an optimal scalar map corresponding to the sign function.

(iv) Our current best known upper bounds for $K^\mathbb{R}_G$ and $K^\mathbb{C}_G$ are due to Krivine [13], who in 1979 used Banach space theory and ideas in [14] to get

$$K^\mathbb{R}_G \leq \frac{\pi}{2 \log(1 + \sqrt{2})} \approx 1.78221;$$

$$K^\mathbb{C}_G \leq \frac{2\pi}{\log(1 + \sqrt{2})} \approx 2.30994.$$
and Haagerup [9], who in 1987 extended Krivine’s ideas to \( \mathbb{C} \) to get

\[ K_G^\mathbb{C} \leq \frac{8}{\pi(x_0 + 1)} \approx 1.40491, \]

where \( x_0 \in [0, 1] \) is the unique solution to:

\[ x \int_0^{\pi/2} \frac{\cos^2 t}{\sqrt{1 - x^2 \sin^2 t}} dt = \frac{\pi}{8}(x + 1). \]

(v) Our current best known lower bounds for \( K_R^G \) and \( K_G^\mathbb{C} \) are due to Davie [4, 5], who in 1984 used spherical integrals to get

\[ K_R^G \geq \sup_{x \in (0, 1)} \frac{1 - \rho(x)}{\max(\rho(x), f(x))} \approx 1.67696, \]

where

\[ \rho(x) := \sqrt{\frac{2}{\pi}} xe^{-x^2/2}, \quad f(x) := \frac{2}{\pi} e^{-x^2} + \rho(x) \left[ 1 - \sqrt{\frac{8}{\pi}} \int_x^\infty e^{-t^2/2} dt \right]; \]

and

\[ K_G^\mathbb{C} \geq \sup_{x > 0} \frac{1 - \theta(x)}{g(x)} \approx 1.33807, \]

where

\[ \theta(x) := \frac{1}{2} \left[ 1 - e^{-x^2} + x \int_x^\infty e^{-t^2} dt \right], \]

\[ g(x) := \left[ \frac{1}{x}(1 - e^{-x^2}) + \int_x^\infty e^{-t^2} dt \right]^2 + \theta(x) \left[ 1 - \frac{2}{x}(1 - e^{-x^2}) \right]. \]

(vi) Progress on improving the aforementioned bounds halted for many years. Believing that Krivine’s bound is the exact value of \( K_R^G \), some were spurred to find matrices that yield it as the lower bound of \( K_R^G \) [12]. The belief was dispelled in 2011 in a landmark paper [3], which demonstrated the existence of a positive constant \( \varepsilon \) such that \( K_R^G < \pi/(2 \log(1 + \sqrt{2})) - \varepsilon \) but the authors did not provide an explicit better bound. To date, Krivine’s and Haagerup’s bounds remain the best known explicit upper bounds for \( K_R^G \) and \( K_G^\mathbb{C} \) respectively.

(vii) There have also been many alternate proofs of Grothendieck’s inequality employing a variety of techniques, among them factorization of Hilbert spaces [16, 10, 17], absolutely summing operators [7, 14, 18], geometry of Banach spaces [1, 15], metric theory of tensor product [6], basic probability theory [2], bilinear forms on \( C^* \)-algebra [11].

In this article, we will present a proof of Grothendieck’s inequality that unifies both the (a) real and (b) complex cases; and yields both the (c) Krivine and (d) Haagerup bounds [13, 9]. It is also elementary in that it requires little more than calculus. Our proof will rely on Lemma 2.1, which is a variation of known ideas in [14, 9, 10]. In particular, the idea of using the sign function to establish (1) in the real case was due to Grothendieck himself [8] and later also appeared in [14, 13]; whereas the use of the sign function in the complex case first appeared in [9]. To be clear, all the key ideas in our proof were originally due to Lindenstrauss–Pełczyński, Krivine, and Haagerup [14, 13, 9], our only contribution is pedagogical — combining, simplifying, and streamlining their ideas into what we feel is a more palatable proof.

One consequence of an earlier article by two of the authors [20] is that Grothendieck’s inequality may be expressed in an equivalent simple form:

\[ \max_{\|X,Y,M\| \neq 0} \frac{|\text{tr}(XMY)|}{\|X\|_{1,2}\|Y\|_{2,\infty}\|M\|_{\infty,1}} \leq K_G^\mathbb{R}, \]
for matrices $M \in \mathbb{F}^{m \times n}$, $X \in \mathbb{F}^{l \times m}$, and $Y \in \mathbb{F}^{n \times l}$. The characterization \cite{2} holds over both $\mathbb{F} = \mathbb{R}$ and $\mathbb{C}$. We will prove Grothendieck’s inequality in the form \cite{2} in Theorem 4.1.

The matrix $(p,q)$-norms involved are
\[\|X\|_{1,2} := \max_{z \neq 0} \frac{\|Xz\|_2}{\|z\|_1} = \max_{i=1, \ldots, m} \|x_i\|_2, \quad \|Y\|_{2,\infty} := \max_{z \neq 0} \frac{\|Yz\|_\infty}{\|z\|_2} = \max_{i=1, \ldots, n} \|y_i\|_2,\]
where $x_1, \ldots, x_m$ are the columns of $X \in \mathbb{F}^{l \times m}$ and $y_1, \ldots, y_n$ are the rows of $Y \in \mathbb{F}^{n \times l}$; also
\[\|M\|_{\infty,1} := \max_{z \neq 0} \frac{\|Mz\|_1}{\|z\|_\infty} = \max_{|\varepsilon_i|=1,|\delta_j|=1} \left| \sum_{i=1}^m \sum_{j=1}^n M_{ij} \varepsilon_i \delta_j \right| .\]
Throughout this article, our inner product over $\mathbb{C}$ will be sesquilinear in the second argument, i.e.,
\[\langle x, y \rangle := y^* x \quad \text{for all } x, y \in \mathbb{C}^n.\]

2. Gaussian integral of sign function

For $z \in \mathbb{F} = \mathbb{R}$ or $\mathbb{C}$, the sign function is
\[\text{sgn}(z) = \begin{cases} z/|z| & \text{if } z \neq 0, \\ 0 & \text{if } z = 0; \end{cases}\]
and for $z \in \mathbb{F}^n$, the Gaussian function is
\[G^\mathbb{F}_n(z) = \begin{cases} (2\pi)^{-n/2} \exp\left(-\|z\|_2^2/2\right) & \text{if } \mathbb{F} = \mathbb{R}, \\ \pi^{-n} \exp(-\|z\|_2^2) & \text{if } \mathbb{F} = \mathbb{C}. \end{cases}\]

Lemma 2.1 below is based on \cite{10, 9}; the complex version in particular is a slight variation of \cite{9, Lemma 3.2}. It plays an important role in our proof because the right side of \cite{3} depends only on the inner product $\langle u, v \rangle$ and not (explicitly) on the dimension $n$. In addition, the functions on the right are homeomorphisms and admit Taylor expansions, making it possible to expand them in powers $\langle u, v \rangle^d = \langle u^{\otimes d}, v^{\otimes d} \rangle$, which will come in useful when we prove Theorem 4.1.

Lemma 2.1. Let $u, v \in \mathbb{F}^n$ with $\|u\|_2 = \|v\|_2 = 1$. Then
\begin{equation}
\int_{\mathbb{F}^n} \text{sgn}(u, z) \text{sgn}(z, v) G^\mathbb{F}_n(z) \, dz = \begin{cases} \frac{2}{\pi} \arcsin \langle u, v \rangle & \text{if } \mathbb{F} = \mathbb{R}, \\ \langle u, v \rangle \int_0^{\pi/2} \frac{\cos^2 t}{(1 - |\langle u, v \rangle|^2 \sin^2 t)^{1/2}} \, dt & \text{if } \mathbb{F} = \mathbb{C}. \end{cases}
\end{equation}

Proof. Case I: $\mathbb{F} = \mathbb{R}$. Let $\arccos(u, v) = \theta$, so that $\theta \in [0, \pi]$ and $\arcsin(u, v) = \pi/2 - \theta$. Choose $\alpha, \beta$ such that $0 < \beta - \alpha < \pi$ and define
\[E(\alpha, \beta) = \{(r \cos \theta, r \sin \theta, x_3, \ldots, x_n) : r \geq 0, \alpha \leq \theta \leq \beta\}.
\]
The Gaussian measure of a measurable set $A$ is the integral of $G^\mathbb{F}_n(x)$ over $A$. Upon integrating with respect to $x_3, \ldots, x_n$, the following term remains:
\[\frac{1}{2\pi} \int_{E(\alpha, \beta)} e^{-\frac{1}{2}(x_1^2 + x_2^2)} \, dx_1 \, dx_2 = \frac{1}{2\pi} \int_0^\beta d\theta \int_0^\infty r e^{-\frac{1}{2}r^2} \, dr = (\beta - \alpha)/2\pi.
\]
Hence the Gaussian measure of $E(\alpha, \beta)$ is $(\beta - \alpha)/2\pi$. Since there is an isometry $T$ of $\mathbb{R}^n$ such that $Tu = e_1$ and $Tv = (\cos \theta, \sin \theta, 0, \ldots, 0)$, the left side of \cite{3} may be expressed as
\[\int_{\mathbb{R}^n} \text{sgn}(Tu, x) \text{sgn}(x, Tv) G^\mathbb{F}_n(x) \, dx.
\]
The set of $x$ where $\langle Tu, x \rangle > 0$ and $\langle Tv, x \rangle > 0$ is $E(\theta - \pi/2, \pi/2)$, which has Gaussian measure $(\pi - \theta)/2\pi$; ditto for $\langle Tu, x \rangle < 0$ and $\langle Tv, x \rangle < 0$. The set of $x$ where $\langle Tu, x \rangle < 0$ and $\langle Tv, x \rangle > 0$
is $E(\pi/2, \theta + \pi/2)$, which has Gaussian measure $\theta/2\pi$; ditto for $\langle Tu, x \rangle > 0$ and $\langle Tv, x \rangle < 0$. Hence the value of this integral is $(\pi - \theta)/2\pi + (\pi - \theta)/2\pi - \theta/2\pi = 2\arcsin(u, v)/\pi$.

**Case II:** $\mathbb{F} = \mathbb{C}$. We define vectors $\alpha, \beta \in \mathbb{R}^{2n}$ with $\alpha_{2i-1} = \Re(u_i), \alpha_{2i} = \Im(u_i), \beta_{2i-1} = \Re(v_i), \beta_{2i} = \Im(v_i), i = 1, \ldots, n$. Then $\alpha$ and $\beta$ are unit vectors in $\mathbb{R}^{2n}$. For any $z = (z_1, \ldots, z_n) \in \mathbb{C}^n$, we write

$$x = (\Re(z_1), \Im(z_1), \ldots, \Re(z_n), \Im(z_n)) \in \mathbb{R}^{2n}.$$

Then,

$$\Re(\langle u, z \rangle) = \sum_{i=1}^{n} \Re(u_i z_i) = \sum_{i=1}^{n} (\Re(u_i) \Re(z_i) + \Im(u_i) \Im(z_i)) = \langle \alpha, x \rangle = \langle x, \alpha \rangle,$$

and likewise $\Re(\langle z, v \rangle) = \langle x, \beta \rangle$. By a change-of-variables and Case I, we have

$$\int_{\mathbb{C}^n} \text{sgn}(\Re(\langle u, z \rangle)) \text{sgn}(\Re(\langle z, v \rangle)) G_n^{\mathbb{C}}(z) \, dz = \int_{\mathbb{R}^{2n}} \text{sgn}(x, \alpha) \text{sgn}(x, \beta) G_{2n}^{\mathbb{R}}(x) \, dx$$

$$= \frac{2}{\pi} \arcsin(\alpha, \beta) = \frac{2}{\pi} \arcsin(\Re(\langle u, v \rangle)).$$

It is easy to verify that for any $z \in \mathbb{C}$,

$$\text{sgn}(z) = \frac{1}{4} \int_{0}^{2\pi} \text{sgn}(\Re(e^{-i\theta} z)) e^{i\theta} \, d\theta.$$

By [4], [5], and Fubini’s theorem,

$$\int_{\mathbb{C}^n} \text{sgn}(\langle u, z \rangle) \text{sgn}(\langle z, v \rangle) G_n^{\mathbb{C}}(z) \, dz$$

$$= \frac{1}{16} \int_{0}^{2\pi} \int_{0}^{2\pi} \int_{\mathbb{C}^n} \text{sgn}(\langle e^{-i\theta} u, z \rangle) \text{sgn}(\langle z, e^{-i\varphi} v \rangle) e^{i(\theta + \varphi)} G_n^{\mathbb{C}}(z) \, dz \, d\theta \, d\varphi$$

$$= \frac{1}{8\pi} \int_{0}^{2\pi} \int_{0}^{2\pi} \text{arcsin}(\langle e^{-i\theta} u, e^{i\varphi} v \rangle) e^{i(\theta + \varphi)} \, d\theta \, d\varphi.$$

**Case II(a):** $\langle u, v \rangle \in \mathbb{R}$. The integral above becomes

$$= \frac{1}{8\pi} \int_{0}^{2\pi} \left[ \int_{0}^{2\pi} \text{arcsin}(\cos(\theta + \varphi) \langle u, v \rangle) e^{i(\theta + \varphi)} \, d\theta \right] \, d\varphi$$

$$= \frac{1}{8\pi} \int_{0}^{2\pi} \left[ \int_{0}^{2\pi + \varphi} \text{arcsin}(\langle u, v \rangle \cos t) e^{it} \, dt \right] \, d\varphi$$

$$= \frac{1}{8\pi} \int_{0}^{2\pi} \left[ \int_{0}^{2\pi} \text{arcsin}(\langle u, v \rangle \cos t) e^{it} \, dt \right] \, d\varphi = \frac{1}{4} \int_{0}^{2\pi} \text{arcsin}(\langle u, v \rangle \cos t) e^{it} \, dt.$$

Since $\text{arcsin}(\langle u, v \rangle \cos t)$ is an even function with period $2\pi$,

$$\int_{0}^{2\pi} \text{arcsin}(\langle u, v \rangle \cos t) \sin t \, dt = 0,$$

the last integral in (6) becomes

$$\frac{1}{4} \int_{0}^{2\pi} \text{arcsin}(\langle u, v \rangle \cos t) \cos t \, dt,$$

and as $\text{arcsin}(\langle u, v \rangle \cos t) \cos t$ is an even function with period $\pi$, it becomes

$$\int_{0}^{\pi/2} \text{arcsin}(\langle u, v \rangle \cos t) \cos t \, dt = \int_{0}^{\pi/2} \text{arcsin}(\langle u, v \rangle \sin t) \sin t \, dt.$$
which, upon integrating by parts, becomes
\[
\langle u, v \rangle \int_0^{\pi/2} \frac{\cos^2 t}{(1 - |\langle u, v \rangle|^2 \sin^2 t)^{1/2}} dt.
\]

Case II(b): \( \langle u, v \rangle \notin \mathbb{R} \). This reduces to Case II(a) by setting \( c \in \mathbb{C} \) of unit modulus so that \( c\langle u, v \rangle = |\langle u, v \rangle| \) and \( (cu, v) \in \mathbb{R} \), then by (7),
\[
\int_{C^n} \text{sgn}(u, z) \text{sgn}(z, v) G_n^C(z) dz = \int_{C^n} \text{sgn}(cu, z) \text{sgn}(z, v) G_n^C(z) dz
\]
\[
= \langle cu, v \rangle \int_0^{\pi/2} \frac{\cos^2 t}{(1 - |\langle cu, v \rangle|^2 \sin^2 t)^{1/2}} dt = \langle u, v \rangle \int_0^{\pi/2} \frac{\cos^2 t}{(1 - |\langle u, v \rangle|^2 \sin^2 t)^{1/2}} dt.
\]

\( \square \)

In the corollary below, the inequality on the left is the original Grothendieck inequality \([8]\), and the inequality on the right is due to Haagerup \([9]\).

**Corollary 2.2.** Let \( M = (M_{ij}) \in \mathbb{F}^{n \times n} \) be a matrix with \( \|M\|_{\infty, 1} \leq 1 \). Let \( x_1, \ldots, x_m \) and \( y_1, \ldots, y_n \) be unit vectors in a Hilbert space \( \mathcal{H} \) over \( \mathbb{F} \). Then
\[
\left| \sum_{i=1}^m \sum_{j=1}^n M_{ij} \arcsin \langle x_i, y_j \rangle \right| \leq \frac{\pi}{2} \quad \text{if } \mathbb{F} = \mathbb{R}, \quad \left| \sum_{i=1}^m \sum_{j=1}^n M_{ij} H(\langle x_i, y_j \rangle) \right| \leq 1 \quad \text{if } \mathbb{F} = \mathbb{C},
\]
where \( H \) denotes the function on the right side of (3) for \( \mathbb{F} = \mathbb{C} \).

**Proof.** By restricting to a subspace spanned by the unit vectors, we may assume that \( \mathcal{H} = \mathbb{F}^d \) without loss of generality. The condition \( \|M\|_{\infty, 1} \leq 1 \) implies that
\[
\left| \sum_{i=1}^m \sum_{j=1}^n M_{ij} \text{sgn}(x_i, x) \text{sgn}(y_j, x) G_d^\mathbb{F}(z) \right| \leq G_d^\mathbb{F}(z),
\]
\[
\left| \sum_{i=1}^m \sum_{j=1}^n M_{ij} \text{sgn}(z, x_i) \text{sgn}(z, y_j) G_d^C(z) \right| \leq G_d^C(z),
\]
for any \( x \in \mathbb{F}^d, z \in \mathbb{C}^d \) respectively. Integrating over \( \mathbb{F}^d \) or \( \mathbb{C}^d \) respectively and applying Lemma \( \ref{lem:2.1} \), we give the required results. \( \square \)

3. **Haagerup Function**

We will need to make a few observations regarding the functions on the right side of (3) for the proof of Grothendieck’s inequality. Let the complex Haagerup function of a complex variable \( z \) be
\[
H(z) := z \int_0^{\pi/2} \frac{\cos^2 t}{(1 - |z|^2 \sin^2 t)^{1/2}} dt, \quad |z| \leq 1,
\]
and the real Haagerup function \( h \) as the restriction of \( H \) to \([-1, 1] \subseteq \mathbb{R} \). Observe that \( h : [-1, 1] \to [-1, 1] \) and is a strictly increasing continuous bijection. Since \([-1, 1]\) is compact, \( h \) is a homeomorphism of \([-1, 1]\) onto itself. By the Taylor expansion
\[
(1 - x^2 \sin^2 t)^{-1/2} = \sum_{k=0}^\infty \frac{(2k - 1)!!}{(2k)!!} x^{2k} \sin^{2k} t, \quad |x| \leq 1, \quad 0 \leq t < \pi/2,
\]
and
\[
\int_0^{\pi/2} \cos^2 t \sin^{2k} t dt = \frac{\pi}{4(k + 1)} \frac{(2k - 1)!!}{(2k)!!},
\]
we get
\begin{equation}
    h(x) = \sum_{k=0}^{\infty} \frac{\pi}{4(k+1)} \left[ \frac{(2k-1)!!}{(2k)!!} \right]^2 x^{2k+1}, \quad x \in [-1, 1].
\end{equation}

Since $h$ is analytic at $x = 0$ and $h'(0) \neq 0$, its inverse function $h^{-1} : [-1, 1] \to [-1, 1]$ can be expanded in a power series in some neighborhood of $0$

\begin{equation}
    h^{-1}(x) = \sum_{k=0}^{\infty} b_{2k+1} x^{2k+1}.
\end{equation}

One may in principle determine the coefficients using the Lagrange inversion formula:

\begin{equation}
    b_{2k+1} = \frac{1}{(2k+1)!} \lim_{t \to 0} \left[ \frac{d^{2k}}{dt^{2k}} \left( \frac{t}{h(t)} \right)^{2k+1} \right].
\end{equation}

For example,

$\begin{align*}
    b_1 &= \frac{4}{\pi}, \\
    b_3 &= -\frac{1}{8} \left( \frac{4}{\pi} \right)^3, \\
    b_5 &= 0, \\
    b_7 &= -\frac{1}{1024} \left( \frac{4}{\pi} \right)^7.
\end{align*}$

But determining $b_{2k+1}$ explicitly becomes difficult as $k$ gets larger. A key step in Haagerup’s proof \cite{9} requires the nonpositivity of the coefficients beyond the first:

\begin{equation}
    b_{2k+1} \leq 0, \quad \text{for all } k \geq 1.
\end{equation}

This step is in our view the most technical part of \cite{9}. We have no insights on how it may be avoided but we simplified Haagerup’s proof of \cite{11} in Section 5 to keep to our promise of an elementary proof — using only calculus and basic complex variables.

It follows from \cite{11} that $\tilde{h}(z) := b_1 z - h^{-1}(z)$ has nonnegative Taylor coefficients. Pringsheim’s theorem implies that if the radius of convergence of the Taylor series of $\tilde{h}(z)$ is $r$, then $\tilde{h}(z)$, and thus $h^{-1}(z)$, has a singular point at $z = r$. As $h'(t) > 0$ on $(0, 1)$ and $h(1) = 1$, we must have $r \geq 1$. It also follows from \cite{11} that $h^{-1}(t) \leq \sum_{k=0}^{N} b_{2k+1} t^{2k+1}$ for any $t \in (0, 1)$ and $N \in \mathbb{N}$. So $\sum_{k=1}^{N} |b_{2k+1}| t^{2k+1} \leq b_1 t - h^{-1}(t)$ for any $t \in (0, 1)$ and $N \in \mathbb{N}$. So $\sum_{k=1}^{N} |b_{2k+1}| \leq b_1 - 1$ for any $N \in \mathbb{N}$ and we have $\sum_{k=0}^{\infty} |b_{2k+1}| \leq 2b_1 - 1$. As $h^{-1}(1) = 1$ we deduce that $\sum_{k=0}^{\infty} b_{2k+1} = h^{-1}(1) = 1$, and therefore

\begin{equation}
    \sum_{k=0}^{\infty} |b_{2k+1}| = 2b_1 - 1.
\end{equation}

We now turn our attention back to the complex Haagerup function. Observe that $|H(z)| = h(|z|)$ for all $z \in D := \{ z \in \mathbb{C} : |z| \leq 1 \}$ and $\arg(H(z)) = \arg(z)$ for $0 \neq z \in D$. So $H : D \to \mathbb{D}$ is a homeomorphism of $D$ onto itself. Let $H^{-1} : \mathbb{D} \to D$ be its inverse function. Since $H(z) = \text{sgn}(z) h(|z|)$, we get

\begin{equation}
    H^{-1}(z) = \text{sgn}(z) h^{-1}(|z|) = \text{sgn}(z) \sum_{k=0}^{\infty} b_{2k+1} |z|^{2k+1}.
\end{equation}

Dini’s theorem shows that the function $\varphi(x) := \sum_{k=0}^{\infty} |b_{2k+1}| x^{2k+1}$ is a strictly increasing and continuous on $[0, 1]$, with $\varphi(0) = 0$ and $\varphi(1) = \sum_{k=0}^{\infty} |b_{2k+1}| \geq b_1 = 4/\pi > 1$; note that $\varphi(1)$ is finite by \cite{12}. Thus there exists a unique $c_0 \in (0, 1)$ such that $\varphi(c_0) = 1$. So

$$1 = \varphi(c_0) = \sum_{k=0}^{\infty} |b_{2k+1}| c_0^{2k+1} = \frac{8}{\pi} c_0 - h^{-1}(c_0),$$

where the last equality follows from $b_1 = 4/\pi$ and \cite{11}. Therefore we obtain $h^{-1}(c_0) = 8c_0/\pi - 1$, and if we let $x_0 := h^{-1}(c_0) \in (0, 1)$, then $h(x_0) - \pi(x_0 + 1)/8 = 0$. From the Taylor expansion of
\( h(x), \) the function \( x \mapsto h(x) - \pi(x + 1)/8 \) is increasing and continuous on \([0, 1]\\). Hence \( x_0 \) is the unique solution in \([0, 1]\\) to

\[
(14) \quad h(x) - \frac{\pi}{8}(x + 1) = 0
\]

and \( c_0 = \pi(x_0 + 1)/8.\\)

4. A unified proof of Grothendieck’s inequality

In this section, we will derive Grothendieck’s inequality in a way that simultaneously yields Krivine’s and Haagerup’s bounds:

\[
K^\mathbb{F}_G \leq \frac{\pi}{2 \log(1 + \sqrt{2})} =: B^\mathbb{R}, \quad K^\mathbb{C}_G \leq \frac{8}{\pi(x_0 + 1)} =: B^\mathbb{C},
\]

where \( x_0 \) is as defined in \((14)\\).

**Theorem 4.1** (Grothendieck inequality with Krivine and Haagerup bounds). Let \( F = \mathbb{R} \) or \( \mathbb{C} \). For any \( l, m, n \in \mathbb{N} \) and nonzero matrices \( X \in \mathbb{F}^{l \times m}, Y \in \mathbb{F}^{m \times l}, M \in \mathbb{F}^{m \times n} \), we have

\[
(15) \quad \frac{|\text{tr}(XMY)|}{\|X\|_{1,2}\|Y\|_{2,\infty}\|M\|_{\infty,1}} \leq B^F.
\]

**Proof.\)** Observe that over \( \mathbb{C} \), since \( \|Y\|_{2,\infty} = \|Y\|_{2,\infty} \)

\[
\max_{X,Y,M \neq 0} \frac{|\text{tr}(XMY)|}{\|X\|_{1,2}\|Y\|_{2,\infty}\|M\|_{\infty,1}} = \max_{X,Y,M \neq 0} \frac{|\text{tr}(XMY)|}{\|X\|_{1,2}\|Y\|_{2,\infty}\|M\|_{\infty,1}},
\]

So it suffices to show that \( |\text{tr}(XMY)| \leq B^F \) whenever \( \|X\|_{1,2} \leq 1, \|Y\|_{2,\infty} \leq 1, \|M\|_{\infty,1} \leq 1 \). Let \( X = [x_1, x_2, \ldots, x_m] \) and \( Y^T = [y_1, y_2, \ldots, y_n] \). Then

\[
\text{tr}(XMY) = \sum_{i=1}^m \sum_{j=1}^n M_{ij} \langle x_i, y_j \rangle
\]

over both \( \mathbb{R} \) and \( \mathbb{C} \). By the expressions for matrix \((p, q)\)-norms after \((2)\\), \( \|X\|_{1,2} \leq 1 \) and \( \|Y\|_{2,\infty} \leq 1 \) are equivalent to their column vectors \( x_1, \ldots, x_m \) and row vectors \( y_1, \ldots, y_n \) lying in the closed unit ball of \( \mathbb{F}^l \). Since \( \text{tr}(XMY) \) is linear/sesquilinear, therefore convex, in each factor when the other two are fixed, it attains the maximum in that factor at an extreme point of the unit ball in the respective norm. As such, we may further assume that all \( x_i \)'s and \( y_j \)'s are unit vectors.

**Case I:** \( F = \mathbb{R} \). Let \( c := \text{arcsinh}(1) = \log(1 + \sqrt{2}) \). Taylor expansion gives

\[
(16) \quad \sin(c(x_i, y_j)) = \sum_{k=0}^\infty (-1)^k \frac{c^{2k+1}}{(2k+1)!} \langle x_i, y_j \rangle^{2k+1} = \sum_{k=0}^\infty (-1)^k \frac{c^{2k+1}}{(2k+1)!} \langle x_i^{\otimes (2k+1)}, y_j^{\otimes (2k+1)} \rangle.
\]

Let \( T(x_i) \) and \( S(y_j) \) be vectors in the direct product \( \prod_{k=0}^\infty (\mathbb{R}^l)^{\otimes (2k+1)} \) whose \( k \)-th coordinates are given respectively by:

\[
T(x_i)_k = (-1)^k \sqrt{\frac{c^{2k+1}}{(2k+1)!}} \cdot x_i^{\otimes (2k+1)} \quad \text{and} \quad S(y_j)_k = \sqrt{\frac{c^{2k+1}}{(2k+1)!}} \cdot y_j^{\otimes (2k+1)}.
\]

The vector space \( \prod_{k=0}^\infty (\mathbb{R}^l)^{\otimes (2k+1)} \) may be given an inner product in the natural way:

\[
\langle T, S \rangle := \sum_{k=0}^\infty \langle T_k, S_k \rangle_k
\]
where $\langle \cdot, \cdot \rangle_k$ denotes the inner product on tensor product space $(\mathbb{R}^l)^{\otimes(2k+1)}$ induced by the inner product on $\mathbb{R}^l$. This also holds with $\mathbb{C}$ in place of $\mathbb{R}$. With this inner product, (16) becomes:

$$\sin(c\langle x_i, y_j \rangle) = \langle T(x_i), S(y_j) \rangle \quad \text{or} \quad c\langle x_i, y_j \rangle = \arcsin\langle T(x_i), S(y_j) \rangle.$$  

Moreover, since $x_i$ and $y_j$ are unit vectors in $\mathbb{R}^l$, we get

$$\|T(x_i)\|^2 = \sinh(c\|x_i\|^2) = 1 \quad \text{and} \quad \|S(y_j)\|^2 = \sinh(c\|y_j\|^2) = 1.$$  

So we may apply Corollary 2.2 to obtain

$$|\text{tr}(XMY)| = \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} \langle x_i, y_j \rangle \right| = \frac{1}{c} \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} \arcsin\langle T(x_i), S(y_j) \rangle \right| \leq \frac{\pi}{2c},$$

which is Krivine’s bound since $\pi/2c = \pi/\left(2\log(1 + \sqrt{2})\right) = B^\mathbb{R}$.

**Case II: $F = \mathbb{C}$.** Let $c_0 \in (0, 1)$ be the unique constant defined in (14) such that $\varphi(c_0) = 1$. By the Taylor expansion in (13),

$$H^{-1}(c_0\langle x_i, y_j \rangle) = \text{sgn}(c_0\langle x_i, y_j \rangle) \sum_{k=0}^{\infty} b_{2k+1} |c_0\langle x_i, y_j \rangle|^{2k+1}$$

$$= \text{sgn}(\langle x_i, y_j \rangle) \sum_{k=0}^{\infty} b_{2k+1} |\langle x_i, y_j \rangle|^{2k+1} c_0^{2k+1}$$

$$= \sum_{k=0}^{\infty} b_{2k+1}(\text{sgn}(\langle x_i, y_j \rangle))^{2k} c_0^{2k+1} \langle x_i^{\otimes(2k+1)}, y_j^{\otimes(2k+1)} \rangle,$$

where we adopt the convention that any term with $\langle x_i, y_j \rangle = 0$ is omitted from the sum in (17).

Analogous to Case I, we define vectors $T(x_i)$ and $S(y_j)$ in the direct product $\prod_{k=0}^{\infty}(\mathbb{C}^l)^{\otimes(2k+1)}$ whose $k$th coordinates are given respectively by:

$$T(x_i)_k = \frac{\text{sgn}(b_{2k+1})}{(\text{sgn}(\langle x_i, y_j \rangle))^{2k}} \left( |b_{2k+1}| c_0^{2k+1} \right)^{1/2} \cdot x_i^{\otimes(2k+1)},$$

$$S(y_j)_k = \left( |b_{2k+1}| c_0^{2k+1} \right)^{1/2} \cdot y_j^{\otimes(2k+1)}$$

where again any term with $\langle x_i, y_j \rangle = 0$ is taken to be $0$ in the definition of $T(x_i)_k$. As in Case I, we may rewrite (17) as

$$H^{-1}(c_0\langle x_i, y_j \rangle) = \langle T(x_i), S(y_j) \rangle \quad \text{or} \quad c_0\langle x_i, y_j \rangle = H((T(x_i), S(y_j))).$$

Moreover, since $x_i$ and $y_j$ are unit vectors in $\mathbb{C}^l$, we get

$$\|T(x_i)\|^2 = \sum_{k=0}^{\infty} |b_{2k+1}| c_0^{2k+1} = \varphi(c_0) = 1$$

and likewise $\|S(y_j)\|^2 = 1$. So we may apply Corollary 2.2 to get

$$|\text{tr}(XMY)| = \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} \langle x_i, y_j \rangle \right| = \frac{1}{c_0} \left| \sum_{i=1}^{m} \sum_{j=1}^{n} M_{ij} H((\langle T(x_i), S(y_j) \rangle) \right| \leq \frac{1}{c_0},$$

which is Haagrep’s bound since $1/c_0 = 8/\pi(x_0 + 1) = B^\mathbb{C}$.  \qed
5. Nonpositivity of \( b_{2k+1} \)

To make the proof in this article entirely self-contained, we present Haagerup’s proof of the nonpositivity of \( b_{2k+1} \) that we used earlier in (11). While the main ideas are all due to Haagerup, our small contribution here is that we avoided the use of any known results of elliptic integrals in order to stay faithful to our claim of an elementary proof, i.e., one that uses only calculus and basic complex variables. To be clear, while the functions

\[
K(x) := \int_0^{\pi/2} (1 - x^2 \sin^2 t)^{-1/2} dt, \quad E(x) := \int_0^{\pi/2} (1 - x^2 \sin^2 t)^{1/2} dt
\]

do make a brief appearance in the proof of Lemma 5.1, the reader does not need to know that they are the complete elliptic integrals of the first and second kinds respectively. Haagerup had relied liberally on properties of \( K \) and \( E \) that require substantial effort to establish in his proof [9]. We will only use trivialities that follow immediately from (18).

Our point of departure from Haagerup’s proof is the following lemma about two functions \( h_1 \) and \( h_2 \), which we will see in Lemma 5.2 arise respectively from the real and imaginary parts of the analytic extension of the real Haagerup function \( h : [-1, 1] \to [-1, 1] \) to the upper half plane.

**Lemma 5.1.** Let \( h_1, h_2 : [1, \infty) \to \mathbb{R} \) be defined by

\[
h_1(x) := \int_0^{\pi/2} \sqrt{1 - x^{-2}} \sin^2 t \ dt, \quad h_2(x) := (1 - x^{-2}) \int_0^{\pi/2} \frac{\sin^2 t}{\sqrt{1 - (1 - x^{-2}) \sin^2 t}} \ dt,
\]

which are clearly strictly increasing functions on \([1, \infty)\) with

\[
h_1(1) = 1, \quad \lim_{x \to \infty} h_1(x) = \pi/2, \quad h_2(1) = 0, \quad \lim_{x \to \infty} h_2(x) = \infty.
\]

Then

\[
\omega_1(x) := x(h_1(x)h_2'(x) - h_1'(x)h_2(x)) = \frac{\pi}{2} \quad \text{for } x \geq 1,
\]

\[
\omega_2(x) := x(h_1(x)h_1'(x) + h_2(x)h_2'(x)) \geq 2h_1(\sqrt{2})h_2(\sqrt{2}) > \frac{\pi}{4} \quad \text{for } 1 \leq x \leq \sqrt{2}.
\]

**Proof.** We start by observing some properties of \( h_1' \) and \( h_2' \). As

\[
h_1'(x) = \frac{1}{x^3} \int_0^{\pi/2} \frac{\sin^2 t}{\sqrt{1 - x^{-2}} \sin^2 t} dt = \frac{1}{x^2} \int_0^{\pi/2} \frac{\sin^2 t}{\sqrt{x^2 - \sin^2 t}} dt,
\]

\( h_1' \) is strictly decreasing on \((1, \infty)\). As \( \int_0^{\pi/2} \cos^{-1} t \ dt = \infty \), \( \lim_{x \to 1^+} h_1'(x) = \infty \). Clearly \( \lim_{x \to \infty} h_1'(x) = 0 \). Furthermore, when \( x > 1 \), since \( \sqrt{x^2 - \sin^2 t} \geq \sqrt{x^2 - 1} \), we have

\[
0 < h_1'(x) \leq \frac{\pi}{4x^2 \sqrt{x^2 - 1}} \text{ for } x > 1.
\]

It is straightforward to see that the functions \( E \) and \( K \) in (18) have derivatives given by

\[
E'(y) = \frac{1}{y} \left(E(y) - K(y)\right), \quad K'(y) = \frac{1}{y(1 - y^2)} \left(E(y) - (1 - y^2)K(y)\right).
\]

Clearly, \( h_2(x) = K(x) - E(x) \), where \( y = y(x) = \sqrt{1 - x^{-2}} \). So by chain rule,

\[
h_2'(x) = y'(x) \frac{d}{dy}(K - E)(y(x)) = \frac{1}{x} \int_0^{\pi/2} (1 - (1 - x^{-2}) \sin^2 t)^{1/2} dt.
\]

Hence \( h_2' \) is strictly decreasing on \([1, \infty)\), \( h_2'(1) = \pi/2 \), and \( \lim_{x \to \infty} h_2'(x) = 0 \).
To show (19), observe that
\[ h_1(x) = E(1/x), \quad xh_1'(x) = K(1/x) - E(1/x), \quad h_2(x) = K(y) - E(y), \quad xh_2'(x) = E(y), \]
where again \( y = \sqrt{1 - x^{-2}} \). Hence
\[
\omega_1(x) = E(1/x)E(y) - [K(1/x) - E(1/x)][K(y) - E(y)] = E(1/x)K(y) + K(1/x)E(y) - K(1/x)K(y).
\]

Computing \( \omega_1' \), we see from (22) that \( \omega_1' \equiv 0 \). So \( \omega_1 \) is a constant function. By (21), \( \lim_{x \to 1} h_1'(x)(1 - x^{-2}) = 0 \), and so \( \lim_{x \to 1} \omega_1(x) = \pi/2 \). Thus \( \omega_1(x) = \pi/2 \) for all \( x > 1 \) and we may set \( \omega_1(1) = \pi/2 \).

We now show (20) following Haagerup’s arguments. Note that
\[
\omega_2(x) = E(1/x)(K(1/x) - E(1/x)) + E(y)(K(y) - E(y)).
\]
Let \( g(x) := E(\sqrt{x})K(1/x) - E(\sqrt{x}) \). A straightforward calculation using (22) shows that
\[
g''(x) = \frac{1}{2} \left[ \frac{E(\sqrt{x})}{x} - \frac{K(\sqrt{x}) - E(\sqrt{x})}{x} \right]^2 \geq 0, \quad x \in [0, 1].
\]
So \( g \) is convex on \([0, 1]\). Hence \( g(1 - x) \) is also convex on \([0, 1]\). Let \( f(x) := g(x) + g(1 - x) \). Then \( f \) is convex on \([0, 1]\) and \( f'(1/2) = 0 \). Therefore \( f(x) \geq f(1/2) \geq 2g(1/2) \). This yields the first inequality in (20): \( \omega_2(x) \geq 2h_1(\sqrt{x})h_2(\sqrt{x}) \) for \( x \in [1, \sqrt{2}] \).

The Taylor expansions of \( h_1 \) and \( h_2 \) may be obtained as that in (8),
\[
\begin{align*}
\omega_1(x) & = \frac{\pi}{2} \sum_{k=0}^{\infty} \left[ \frac{(2k)!}{2^{2k}k!^2} \right]^2 \frac{1}{1 - 2k} x^{-2k}, \\
\omega_2(x) & = \frac{\pi}{2} \sum_{k=0}^{\infty} \left[ \frac{(2k)!}{2^{2k}k!^2} \right]^2 \frac{2k}{2k - 1} (1 - x^{-2})^k.
\end{align*}
\]
Approximate numerical values of \( h_1 \) and \( h_2 \) at \( x = \sqrt{2} \) and 4 are calculated\(^1\) to be:
\[
\begin{align*}
h_1(\sqrt{2}) & \approx 1.3506438, \quad h_2(\sqrt{2}) \approx 0.5034307, \quad h_1(4) \approx 1.5459572, \quad h_2(4) \approx 1.7289033.
\end{align*}
\]
The second inequality in (20) then follows from \( 2h_1(\sqrt{2})h_2(\sqrt{2}) \approx 2 \times 1.35064 \times 0.50343 > \pi/4 \). \( \square \)

In the next two lemmas and their proofs, Arg will denote principal argument.

**Lemma 5.2.** Let \( h : [-1, 1] \to [-1, 1] \) be the real Haagerup function as defined in Section 3. Then \( h \) can be extended to a function \( h_+: \overline{\mathbb{H}} \to \mathbb{C} \) that is continuous on the closed upper half-plane \( \overline{\mathbb{H}} = \{ z \in \mathbb{C} : \text{Im}(z) \geq 0 \} \) and analytic on the upper half-plane \( \mathbb{H} = \{ z \in \mathbb{C} : \text{Im}(z) > 0 \} \). In addition, \( h_+ \) has the following properties:

(i) \( \text{Im}(h_+(z)) \geq \text{Im}(h_+(|z|)) \) for all \( z \in \overline{\mathbb{H}} \cap \{ z \in \mathbb{C} : |z| \geq 1 \} \) and \( h_+(z) \neq 0 \) for all \( z \in \overline{\mathbb{H}} \setminus \{ 0 \} \).

(ii) For \( x \in [1, \infty), \)
\[
\text{Re}(h_+(x)) = h_1(x), \quad \text{Im}(h_+(x)) = h_2(x),
\]

(iii) For all \( k \in \mathbb{N} \) and all real \( \alpha > 1 \),
\[
b_{2k+1} = \frac{2}{\pi(2k+1)} \int_1^{\alpha} \text{Im}(h_+(x))^{-2k} dx + r_k(\alpha)
\]
where
\[
|r_k(\alpha)| \leq \frac{\alpha}{2k+1} \left( \text{Im}(h_+(\alpha)) \right)^{-(2k+1)}.
\]

\(^1\)For example, using [http://www.wolframalpha.com](http://www.wolframalpha.com) which is freely available. Such numerical calculations cannot be completely avoided — Haagerup’s proof implicitly contains them as he used tabulated values of elliptic integrals.
Proof. Integrating by parts, we obtain
\[ h(x) = \int_0^{\pi/2} \cos t \cdot d(\arcsin(x \sin t)) = \int_0^{\pi/2} \sin t \arcsin(x \sin t) \, dt, \quad x \in [-1, 1]. \]

The analytic function \( \sin z \) is a bijection of \([-\pi/2, \pi/2] \times [0, \infty) \) onto \( \mathbb{H} \) and it maps the line segment \( \{ t + ia : -\pi/2 \leq t \leq \pi/2 \} \) onto the half ellipsoid \( \{ z \in \mathbb{H} : |z - 1| + |z + 1| = 2 \cosh a \} \). Let \( \arcsin_+ \) be the inverse of this mapping. Then \( \arcsin_+ \) is continuous in \( \mathbb{H} \) and analytic in \( \mathbb{H} \). In addition, we have:

\[
\arcsin_+ z = \begin{cases} 
\arcsin x & \text{if } x \in [-1, 1], \\
\frac{1}{2} \text{sgn } x + i \arccosh |x| & \text{if } x \in (-\infty, -1) \cup (1, \infty),
\end{cases}
\]

\[
\text{Im}(\arcsin_+ z) = \text{arccosh} \left( \frac{1}{2}(|z - 1| + |z + 1|) \right), \quad z \in \mathbb{H}.
\]

If we define
\[
h_+(z) := \int_0^{\pi/2} \sin t \arcsin_+(z \sin t) \, dt, \quad z \in \mathbb{H},
\]
then \( h_+ \) is a continuous extension of \( h \) to \( \mathbb{H} \) and is analytic in \( \mathbb{H} \).

(i) Since \( \text{arccosh} \) is increasing on \([1, \infty)\), we have
\[
\text{Im}(\arcsin_+ z) = \text{arccosh} \left( \frac{1}{2}(|z - 1| + |z + 1|) \right) \geq \begin{cases} 
\text{arccosh } |z| & \text{if } |z| \geq 1, \\
0 & \text{if } |z| < 1.
\end{cases}
\]

Therefore for \( z \in \mathbb{H} \cap \{ z \in \mathbb{C} : |z| \geq 1 \} \),
\[
\text{Im}(h_+(z)) = \int_0^{\pi/2} \sin t \cdot \text{Im}(\arcsin_+(z \sin t)) \, dt \\
\geq \int_{\text{arcsin}(1/|z|)}^{\pi/2} \sin t \text{arccosh}(|z| \sin t) \, dt = \text{Im}(h_+(|z|)).
\]

As \( \text{Im}(\arcsin_+ z) > 0 \) on \( \mathbb{H} \), we have \( \text{Im}(h_+(z)) > 0 \) on \( \mathbb{H} \). For \( x \in [-1, 1] \), \( h_+(x) = h(x) \) is zero only at \( x = 0 \). For \( x \in (-\infty, -1) \cup (1, \infty) \),
\[
\text{Im}(h_+(x)) = \int_{\text{arcsin}(1/|x|)}^{\pi/2} \sin t \text{arccosh}(|x| \sin t) \, dt > 0.
\]

Hence \( h_+ \) has no zero in \( \mathbb{H} \setminus \{ 0 \} \).

(ii) Let \( x \in (1, \infty) \). Integrating by parts followed by a change-of-variables \( \sin u = x \sin t \) in the next-to-last equality gives us:
\[
\text{Re}(h_+(x)) = \int_0^{\text{arcsin}(1/x)} \sin t \arcsin(x \sin t) \, dt + \frac{\pi}{2} \int_{\text{arcsin}(1/x)}^{\pi/2} \sin t \, dt \\
= x \int_0^{\text{arcsin}(1/x)} \frac{\cos^2 t}{\sqrt{1 - x^2 \sin^2 t}} \, dt = \int_0^{\pi/2} \frac{\cos^2 t}{\sqrt{1 - x^{-2} \sin^2 u}} \, du = h_1(x).
\]

A change-of-variables \( \sin v = (1 - x^{-2})^{-1/2} \cos t \) in the next-to-last equality gives us:
\[
\text{Im}(h_+(x)) = \int_{\text{arcsin}(1/x)}^{\pi/2} \sin t \text{arccosh}(x \sin t) \, dt = x \int_{\text{arcsin}(1/x)}^{\pi/2} \frac{\cos^2 t}{\sqrt{x^2 \sin^2 t - 1}} \, dt \\
= (1 - x^{-2}) \int_0^{\pi/2} \frac{\sin^2 v}{\sqrt{1 - (1 - x^{-2}) \sin^2 v}} \, dv = h_2(x).
\]
(iii) The power series (5) shows that $h$ defines an analytic function $h(z)$ in the open unit disk that is identically equal to $h_+(z)$ on $\{ z \in \mathbb{C} : |z| < 1 \} \cap \mathbb{H}$. Since $h(0) = 0$ and $h'(0) \neq 0$, we can find some $\delta_0 \in (0, 1]$ such that $h(z)$ has an analytic inverse function (6) in $\{ z \in \mathbb{C} : |z| < \delta_0 \}$. For $0 < \delta < \delta_0$, let $C_\delta$ be a counterclockwise orientated circle with radius $\delta$. It follows that $h(C_\delta)$ is a simple closed curve with winding number +1. Integrating by parts with a change-of-variables, we have

$$b_{2k+1} = \frac{1}{2\pi i} \int_{h(C_\delta)} h^{-1}(z) z^{2k+2} dz = \frac{1}{2\pi i} \int_{C_\delta} \frac{z}{h(z)^{2k+2}} h'(z) dz.$$

Note that $b_{2k+1} \in \mathbb{R}$ and

$$-(2k+1) \int_{C_\delta} \frac{zh'(z)}{h(z)^{2k+2}} dz + \int_{C_\delta} \frac{1}{h(z)^{2k+1}} dz = \int_{C_\delta} \frac{dz}{h(z)^{2k+1}} \left[ \frac{z}{h(z)^{2k+1}} \right] dz = 0.$$

Then we get

$$b_{2k+1} = \frac{1}{2\pi(2k+1)} \int_{C_\delta} h(z)^{-(2k+1)} dz = \frac{1}{2\pi(2k+1)} \int_{C_\delta} \text{Im}(h(z)^{-(2k+1)}) dz = \frac{2}{\pi(2k+1)} \int_{C_\delta} \text{Im}(h(z)^{-(2k+1)}) dz$$

where $C_\delta'$ is the quarter circle $\{ \delta e^{i\theta} : 0 \leq \theta \leq \pi/2 \}$. Since $h(z)$ identically equals $h_+(z)$ on $C_\delta'$ and $h_+(z)$ has no zeros in the set $\{ z \in \mathbb{C} : \delta \leq |z| \leq \alpha, \ 0 \leq \text{Arg} z \leq \pi/2 \}$ by \[\Box\]. Cauchy’s integral formula yields

$$b_{2k+1} = \frac{2}{\pi(2k+1)} \text{Im} \left[ \int_\delta^\alpha h_+(z)^{-(2k+1)} dz + \int_{C_\delta'} h_+(z)^{-(2k+1)} dz + \int_{i\alpha} h_+(z)^{-(2k+1)} dz \right].$$

Moreover, since $h_+(z)$ is real on $[\delta, 1]$ and its real part vanishes on the imaginary axis, we are left with

$$b_{2k+1} = \frac{2}{\pi(2k+1)} \int_1^\alpha \text{Im}(h_+(z)^{-(2k+1)}) dz + \frac{2}{\pi(2k+1)} \text{Im} \left[ \int_{C_\alpha'} h_+(z)^{-(2k+1)} dz \right].$$

By \[\Box\], $h_+(z) \geq \text{Im}(h_+(z)) \geq \text{Im}(h_+(|z|))$. Thus

$$\left| \int_{C_\alpha'} h_+(z)^{-(2k+1)} dz \right| \leq \frac{\pi \alpha}{2} \left( \text{Im}(h_+(\alpha)) \right)^{-(2k+1)}.$$

The integral expression of $b_{2k+1}$ in (26) will be an important ingredient in the proof that $b_{2k+1} \leq 0$ for $k \geq 1$. We establish some further approximations for this integral in the next and final lemma.

**Lemma 5.3.** Let $\alpha = 4$ throughout.\[\Box\] Let $\theta(x) := \text{Arg}(h_+(x))$ for $x \in [1, \infty)$. Then $\theta : [1, \infty) \to [0, 2\pi]$ is strictly increasing on for $x \geq 1$, $\theta(1) = 0$, and $\lim_{x \to \infty} \theta(x) = \pi/2$. In addition, we have the following:

(i) Let $p := \lfloor (2k+1)\theta(\alpha)/\pi \rfloor$. Let

$$I_r := \frac{2}{\pi(2k+1)} \int_{\theta(x) = \pi r/(2k+1)}^{\theta(x) = \pi (r+1)/(2k+1)} |h_+(x)|^{-(2k+1)} |\sin((2k+1)\theta(x))| dx$$

for $r = 1, 2, \ldots, p$, and

$$J := \frac{2}{\pi(2k+1)} \int_{\theta(x) = \pi p/(2k+1)}^{\theta(x) = \pi (p+1)/(2k+1)} |h_+(x)|^{-(2k+1)} |\sin((2k+1)\theta(x))| dx.$$
Then
\[ \frac{2}{\pi(2k+1)} \int_1^\alpha \text{Im}(h_+(x)^{-(2k+1)}) \, dx = -I_1 + I_2 - \ldots + (-1)^p I_p + (-1)^{p+1} J. \]

(ii) Let \( k \geq 4 \). Then \( p \geq 2 \) and \( I_1 > I_2 > \ldots > I_p > J \).

(iii) Let \( k \geq 4 \) and \( c = |h_+(\sqrt{2})|e^{-\theta(\sqrt{2})}/2 \). Then \( I_1 > 0.57c^{-(2k+1)}/(2k+1)^2 \) and \( I_2 > 0.85I_1 \).

Proof. Since \( \theta(x) = \arctan(h_2(x)/h_1(x)) \), by \([19]\), we get
\[ \frac{d\theta(x)}{dx} = \frac{h_1(x)h_2'(x) - h_1'(x)h_2(x)}{|h_+(x)|^2} > 0, \quad x > 1. \]

So \( \theta(x) \) is strictly increasing on \( x \geq 1 \). It is clear that \( \theta(1) = 0 \). By Lemma 5.1, \( \lim_{x \to \infty} h_1(x) = \pi/2 \) and \( \lim_{x \to \infty} h_2(x) = +\infty \), so \( \lim_{x \to \infty} \theta(x) = \pi/2 \).

(i) This follows from dividing the interval of the integral \([1, \alpha]\) into \( p+1 \) subsets:
\[ \frac{2}{\pi(2k+1)} \int_1^\alpha |h_+(x)|^{-(2k+1)} \text{Im}(h_+(x)) \, dx = -\frac{2}{\pi(2k+1)} \int_1^\alpha |h_+(x)|^{-(2k+1)} \sin((2k+1)\theta) \, dx = -I_1 + I_2 - \ldots + (-1)^p I_p + (-1)^{p+1} J. \]

(ii) We write \( x = x(\theta) \), \( \theta \in [0, \pi/2] \), for the inverse function of \( \theta = \theta(x) \). By \([28]\), we have
\[ I_r = \frac{4}{\pi^2(2k+1)} \int_{\pi r/(2k+1)}^{\pi (r-1)/(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} |\sin((2k+1)\theta)| \, d\theta, \]
\[ J = \frac{4}{\pi^2(2k+1)} \int_{\pi \theta(\alpha)/(2k+1)}^{\pi \theta(\alpha)/(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} |\sin((2k+1)\theta)| \, d\theta. \]

By Lemma 5.1, \( h_1(x) \) and \( h_2(x) \) are strictly increasing function of \( x \in [1, \infty) \), therefore, so is \( |h_+(x)|^2 = h_1(x)^2 + h_2(x)^2 \). With this, we deduce that \( x|h_+(x)|^{-2k+1} \) is strictly decreasing on \([1, \alpha]\) for \( k \geq 4 \) as
\[ \frac{d}{dx} (x|h_+(x)|^{-2k+1}) = |h_+(x)|^{-2k+1} + \frac{(-2k+1)x}{2} |h_+(x)|^{-2k+1} \frac{d}{dx} |h_+(x)|^2 \]
\[ = |h_+(x)|^{-2k-1} \left( |h_+(x)|^2 - (2k-1)x(h_1(x)h_1'(x) + h_2(x)h_2'(x)) \right) \]
\[ \leq |h_+(x)|^{-2k-1} \left( |h_+(x)|^2 - (2k-1)\frac{7\pi}{4} \right) \approx -0.1187 < 0, \]
where we have used the fact that \( |h_+(x)|^2 \) is increasing on \([1, \alpha]\) in the next-to-last inequality and the numerical value is calculated from those of \( h_1(4) \) and \( h_2(4) \) in \([25]\). Since \( |\sin((2k+1)\theta)| \) is periodic with period \( \pi/(2k+1) \), we obtain \( I_1 > I_2 > \ldots > I_p \). In addition,
\[ J = \frac{4}{\pi^2(2k+1)} \int_{\pi \theta(\alpha)/(2k+1)}^{\pi \theta(\alpha)/\pi(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} |\sin((2k+1)\theta)| \, d\theta < I_p. \]

Finally, we have \( \theta(\alpha) = \arctan(h_1(\alpha)/h_2(\alpha)) \approx 0.8412 > \pi/4 = \arctan(1) \), and so \( p = \lfloor (2k+1)\theta(\alpha)/\pi \rfloor \geq \lfloor 9\theta(\alpha)/\pi \rfloor = 2 \) for \( k \geq 4 \).

(iii) Since \( x(\theta) \geq 1 \) for \( \theta \in [0, \pi/2] \), we have
\[ I_1 \geq \frac{4}{\pi^2(2k+1)} \int_0^{\pi/(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} |\sin((2k+1)\theta)| \, d\theta. \]
Recall that \( \theta = \theta(x) \) and \( x = x(\theta) \) are inverse functions of one another. For \( \theta \in [0, \theta(\sqrt{2})] \),
\[
\frac{d}{d\theta} \log |h_+(x(\theta))| = \frac{1}{2} \frac{d}{dx} \log |h_+(x)|^2 \cdot \left( \frac{d\theta}{dx} \right)^{-1} = h_1(x)h_1'(x) + h_2(x)h_2'(x) = h_1(x)h_2'(x) - h_2(x)h_1'(x) = \frac{\omega_2(x)}{\omega_1(x)} > \frac{1}{2}.
\]
for \( x \in [1, \sqrt{2}] \), we have used \((19), (20)\), and the fact that \( \theta(x) \) is strictly increasing for \( x \geq 1 \). Hence \( \log |h_+(x(\theta))| \leq \log |h_+(\sqrt{2})| - (\theta(\sqrt{2}) - \theta)/2 \) which is equivalent to
\[
|h_+(x(\theta))| \leq ce^{\theta/2}, \quad \theta \in [0, \theta(\sqrt{2})]
\]
where \( c = |h_+(\sqrt{2})|e^{-\theta(\sqrt{2})/2} \approx 1.2059 \) and \( \theta(\sqrt{2}) > \pi/9 \), using values of \( h_1(\sqrt{2}) \) and \( h_2(\sqrt{2}) \) in \((25)\).

It follows that for \( k \geq 4 \), we have
\[
I_1 \geq \frac{4}{\pi^2(2k+1)} \int_0^{\pi/(2k+1)} (ce^{\theta/2})^{-2k+1} \sin((2k+1)\theta) \, d\theta = \frac{4c^{-2k+1}}{\pi^2(2k+1)^2} \int_0^{\pi} e^{-(k-1/2)\theta/(2k+1)} \sin \theta \, d\theta \geq \frac{4c^{-2k+1}}{\pi^2(2k+1)^2} \int_0^{\pi} e^{-\theta/2} \sin \theta \, d\theta = \left( \frac{2c}{\pi} \right)^2 \frac{1}{1+1/4} \frac{c^{-2k+1}}{(2k+1)^2} > 0.57c^{-2k+1}.
\]
Since \( \frac{d}{d\theta} \log |h_+(x(\theta))| \geq 1/2 \), we get
\[
|h_+(x(\theta + \pi/(2k+1)))|^{-2k+1} \leq e^{-(k-1/2)\pi/(2k+1)} |h_+(x(\theta))|^{-2k+1}
\]
Moreover, since \( \theta(5/\sqrt{3}) > 2\pi/9 \), we know that \( x(\theta) \leq 5/\sqrt{3} \) on \([0, 2\pi/9]\). Hence for \( k \geq 4 \), it follows from the above results that
\[
I_r = \frac{4}{\pi^2(2k+1)} \frac{5}{\sqrt{3}} \int_{\pi/(2k+1)}^{2\pi/(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} \sin((2k+1)\theta) \, d\theta \leq \frac{4}{\pi^2(2k+1)} \frac{5}{\sqrt{3}} e^{-(k-1/2)\pi/(2k+1)} \int_0^{\pi/(2k+1)} x(\theta)|h_+(x(\theta))|^{-2k+1} \sin((2k+1)\theta) \, d\theta \leq \frac{5}{\sqrt{3}} e^{-\pi/18} I_1 < 0.85 I_1.
\]

The fact that \( x|h_+(x)|^{-2k+1} \) is strictly decreasing on \([1, 4]\) for \( k \geq 4 \), established in the proof of (ii) above, is a crucial observation for establishing the nonpositivity of \( b_{2k+1} \) for \( k \geq 4 \). Observe that since \( |h_+(x)| \) is strictly increasing for \( x > 1 \), it is enough to show that \( x|h_+(x)|^{-7} \) is strictly decreasing on \([1, 4]\), which is what we did. Note that for a fixed \( k \geq 1 \), \( x|h_+(x)|^{-2k+1} \) is increasing for large enough \( x \), as \( |h_+(x)| \) behaves like \( C \log x \) for \( x \gg 1 \).

**Theorem 5.4.** Let the Taylor expansion of \( h^{-1}(x) \) be as in \((9)\). Then \( b_{2k+1} \leq 0 \) for \( k \geq 1 \).

**Proof.** Let \( k \geq 4 \) and let \( I_1, I_2, \ldots, I_p, J \) be as defined in Lemma 5.3. By \((26)\) with \( \alpha = 4 \) and Lemma 5.3(ii) and (iii), we have
\[
-b_{2k+1} = I_1 - I_2 + \ldots + (-1)^{p-1} I_p + (-1)^p J - r_{2k+1}(5\sqrt{2}) > I_1 - I_2 - r_{2k+1}(5\sqrt{2}).
\]
By \((27)\) and Lemma 5.3(iii) with \( c \approx 1.2059 \) (established in its proof), we get
\[
I_1 - I_2 > \frac{0.0855}{(2k+1)^2} (1.206)^{-(2k+1)}, \quad |r_{2k+1}(4)| \leq \frac{4}{2k+1} (1.728)^{-(2k+1)}.
\]
Since \(-b_{2k+1} > I_1 - I_2 - r_{2k+1}(4)\), we get \(b_{2k+1} < 0\) for \(k \geq 9\). Direct computation using \([10]\) gives us \(b_3, b_5, \ldots, b_{17} \leq 0\), proving nonpositivity for \(k \leq 8\).
